# Week 12

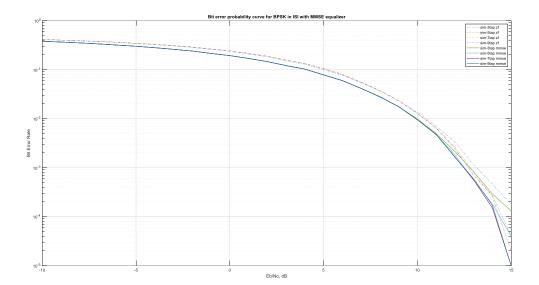

This week, we perform the Huffman source coding<sup>[1]</sup> into the audio file that we want to use. However, we have encountered some problems about the very large matrix sizes. We tried to apply 8-PSK modulation into the encoded data. Our mentor Aslı Taşçı has analyzed the code and suggested us about not to use 8-PSK because of the too much computation we would deal with.

Then, we created an alternative method<sup>[2]</sup> to succeed in the project by applying B-PSK modulation into the random bit data we created ourself. Zero-Forcing and MMSE Equalization methods are applied to the signal. In a real-world BPSK system, the binary data (after being mapped to +1 and -1) is indeed multiplied by a carrier signal. This carrier is usually a high-frequency sinusoidal wave. Because of the simplicity of the data to be processed, carrier multiplication is not applied. For the sake of analysis, especially when focusing on topics like BER performance in the presence of noise or ISI, the carrier component may be omitted to simplify the mathematics. The focus in such cases is often on the baseband signal processing aspects.

BER Analysis: Bit Error Rate (BER) analysis is a critical metric in digital communication systems that counts the fraction of sent bits that are incorrectly received. It is calculated as the ratio of wrongly received bits to total broadcast bits during a certain period. BER is a crucial measure of the quality and dependability of a communication link that is directly influenced by elements such as signal-to-noise ratio (SNR), interference, modulation schemes, and the availability of error correction mechanisms. Essentially, it provides a numerical assessment of a system's performance, assisting engineers and designers in understanding the effectiveness of their communication protocols and hardware under varied operational scenarios. Lower BER values indicate greater system performance, reflecting improved data transmission accuracy and integrity.

P3 - Comparison of Zero Forcing and MMSE Equalizers in Different AWGN Channels

In summary, we applied the different equalization with different tap values on the AWGN channels and applied BER analysis for different SNR values.

**Note:** The analysis of the results and literature search is going to be made in the lab session. Results are going to be compared with the researchments that made in the beginning of the project.
